Molecular Graphics Perspectives of Protein Structure and Function

© 2003, *Theoretical and Computational Biophysics Group, Beckman Institute for Advanced Science and Technology, University of Illinois at Urbana-Champaign*

Large-Scale Structure Visualization

- Large structures: 300,000 atoms and up
- Complex representations
- Long trajectories: thousands of timesteps
- Volumetric data
- Molecular Dynamics: 5 ns simulation of 100K atoms produces a 12GB trajectory

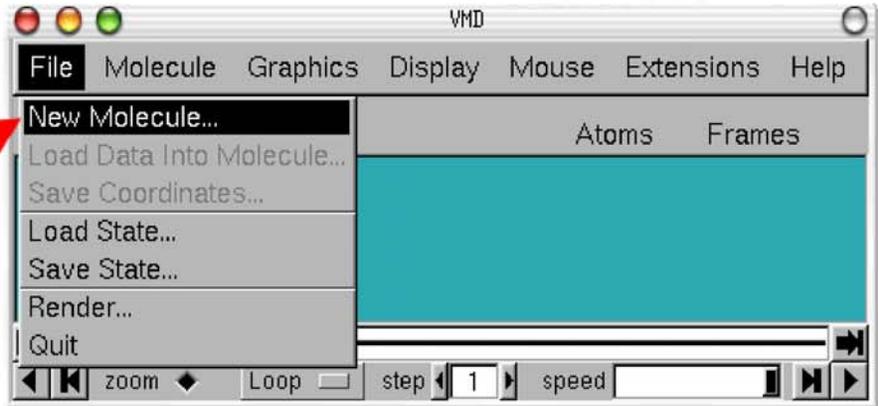

VMD Highlights

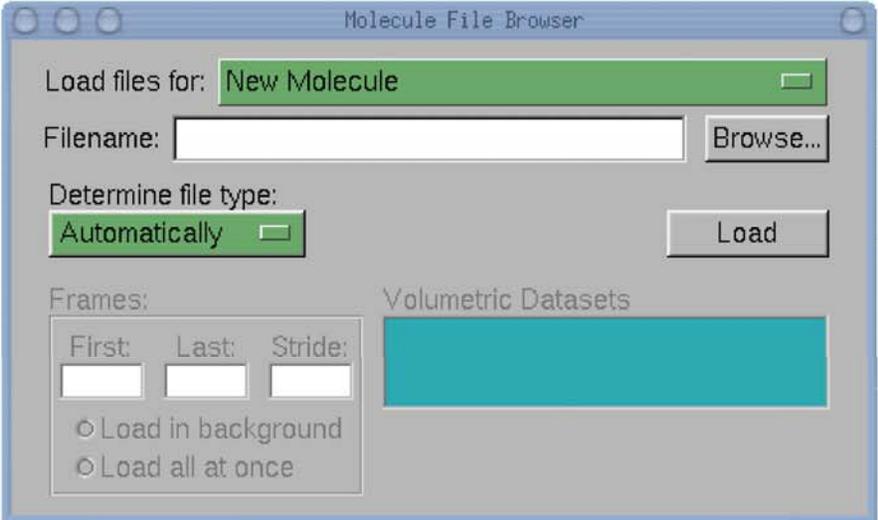

- > 30,000 registered Users
- Platforms:
 - Unix (16 builds)
 - Windows
 - MacOS X
- Display of large biomolecules and simulation trajectories
- Sequence browsing and structure highlighting
- User-extensible scripting interfaces for analysis and customization

Setting Graphics Representations

Rendering a Molecule

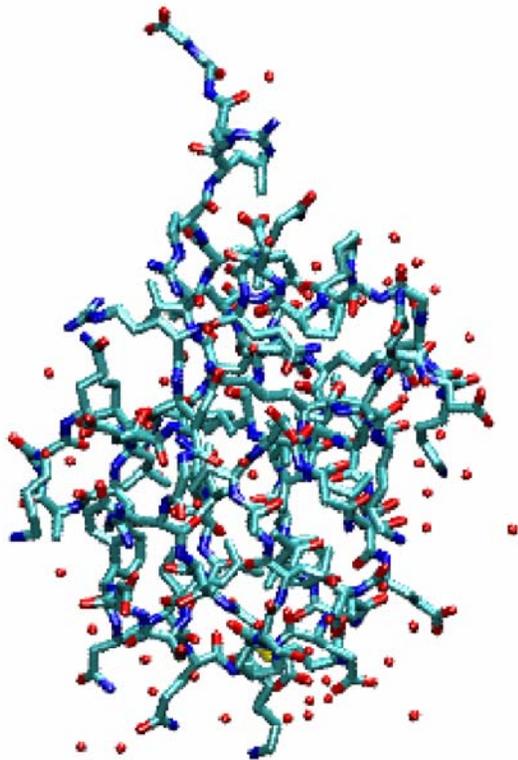

The image shows a software dialog box titled "Graphical Representations" with the following components and annotations:

- Selected Molecule:** A text field containing "0: 1UBQ".
- Buttons:** "Create Rep" and "Delete Rep".
- Table:** A table with columns "Style", "Color", and "Selection". The first row is highlighted in yellow and contains "Lines", "Name", and "all".
- Selected Atoms:** A text field containing "all".
- Draw style:** A tabbed menu with "Draw style" selected.
- Coloring:** A dropdown menu set to "Name".
- Drawing Method:** A dropdown menu set to "Lines".
- Material:** A dropdown menu set to "Opaque".
- Thickness:** A numeric spinner set to "1".
- Apply Changes Automatically:** A checkbox and an "Apply" button.

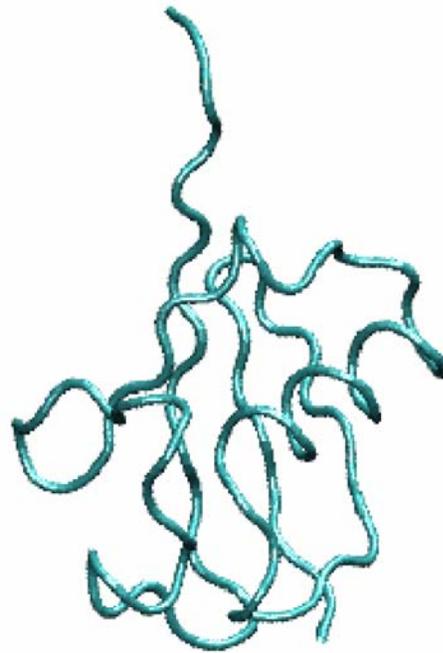

Annotations with red arrows point to the following elements:

- (a) Current graphical representation (points to the highlighted table row)
- (b) Draw style (points to the "Draw style" tab)
- (c) Coloring (points to the "Name" dropdown)
- (d) Drawing method (points to the "Lines" dropdown)
- (e) Resolution, Thickness (points to the "Thickness" spinner)
- (f) Selected Atoms (points to the "Selected Atoms" text field)

Customizing Coloring

Use VMD scripting features to color beta strands separately;

show hydrogen bonds to monitor the mechanical stability of ubiquitin

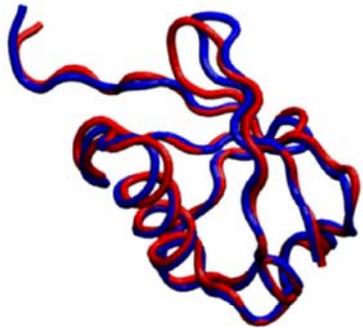

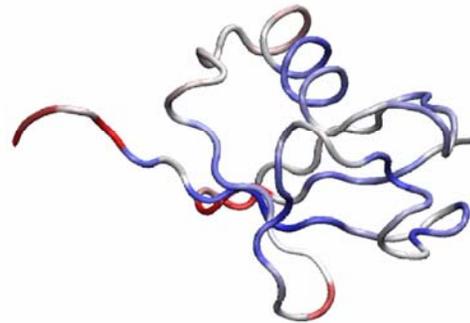

Scripting

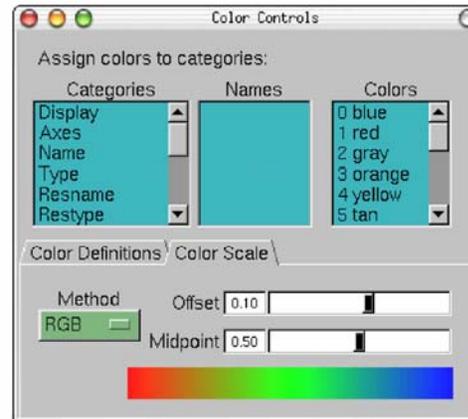

```
VMD TkCon
File Console Edit Interp Prefs History Help
>Main< (tutorial) 57 % puts "Welcome to TkCon!"
Welcome to TkCon!
>Main< (tutorial) 58 % expr -3 + 10
-30
>Main< (tutorial) 59 % set x [expr -3 + 10]
-30
>Main< (tutorial) 60 % puts $x
-30
>Main< (tutorial) 61 % |
```

Tcl and Python supported

Left: Initial and final states of ubiquitin after spatial alignment
Right (top): Color coding of deviation between initial and final

The Color Controls window showing the Color Scale tab.

Introduction to Tcl Syntax

For a scripting language, Tcl has a simple syntax:

```
cmd arg arg arg
```

A Tcl command is formed by words separated by white space. The first word is the name of the command, and the remaining words are arguments to the command.

Introduction to Tcl Syntax

`$foo`

The dollar sign (\$) substitutes the value of a variable. In this example, the variable name is foo.

Introduction to Tcl Syntax

`[clock seconds]`

Square brackets execute a nested command. For example, if you want to pass the result of one command as the argument to another, you use this syntax. In this example, the nested command is `clock seconds`, which gives the current time in seconds.

Introduction to Tcl Syntax

`"some stuff"`

Double quotation marks group words as a single argument to a command. Dollar signs and square brackets are interpreted inside double quotation marks.

Introduction to Tcl Syntax

```
{some stuff}
```

Curly braces also group words into a single argument. In this case, however, elements within the braces are not interpreted.

Introduction to Tcl Syntax

\

The backslash (\) is used to quote special characters. For example, `\n` generates a newline. The backslash also is used to "turn off" the special meanings of the dollar sign, quotation marks, square brackets, and curly braces.

Introduction to Tcl Syntax

Below is a Tcl command that prints the current time. It uses three Tcl commands: set, clock, and puts. The set command assigns the variable. The clock command manipulates time values. The puts command prints the values.

```
set timesec [clock seconds]  
puts "The time is [clock format $timesec]"
```

Note that you do not use \$ when assigning to a variable. Only when you want the value do you use \$. The timesec variable isn't needed in the previous example. You could print the current time with one command:

```
puts "The time is [clock format [clock seconds]]"
```

Introduction to Tcl Syntax

The Tcl syntax is used to guide the Tcl parser through three steps:

- 1. Argument grouping.** Tcl needs to determine how to organize the arguments to the commands. In the simplest case, white space separates arguments. As stated earlier, the quotation marks and braces syntax is used to group multiple words into one argument. In the previous example, double quotation marks are used to group a single argument to the puts command.
- 2. Result substitution.** After the arguments are grouped, Tcl performs string substitutions. Put simply, it replaces \$foo with the value of the variable foo, and it replaces bracketed commands with their result. That substitutions are done *after* grouping is crucial. This sequence ensures that unusual values do not complicate the structure of commands.
- 3. Command dispatch.** After substitution, Tcl uses the command name as a key into a dispatch table. It calls the C procedure identified in the table, and the C procedure implements the command. You also can write command procedures in Tcl. There are simple conventions about argument passing and handling errors.

Introduction to Tcl Syntax

Here is another example:

```
set i 0
while {$i < 10} {
    puts "$i squared = [expr {$i*$i}]"
    incr i
}
```

Here, curly braces are used to **group arguments** without doing any substitutions. The Tcl parser knows nothing special about the while command. It treats it like any other command. It is the implementation of the while command knows that the first argument is an expression, and the second argument is more Tcl commands. The braces group two arguments: the boolean expression that controls the loop and the commands in the loop body. We also see two **math expressions**: the boolean comparison and multiplication. The while command automatically evaluates its first argument as an expression. In other cases you must explicitly use the **expr** command to perform math evaluation.

Introduction to Tcl Syntax

It is very easy to write command procedures. They can do everything from accessing databases to creating graphical user interfaces. Tcl, the language, doesn't really know what the commands do. It just groups arguments, substitutes results, and dispatches commands.

One Last Example:

```
proc fac {x} {
    if {$x < 0} {
        error "Invalid argument $x: must be pos."
    } elseif {$x <= 1} {
        return 1
    } else {
        return [expr {$x * [fac [expr {$x-1}]]}]
    }
}
```
